

Multi-room Space Heater Temperature Control

Eric Menq, Jie Sun, Rong Feng Ye

18500 ECE Design Review Presentation

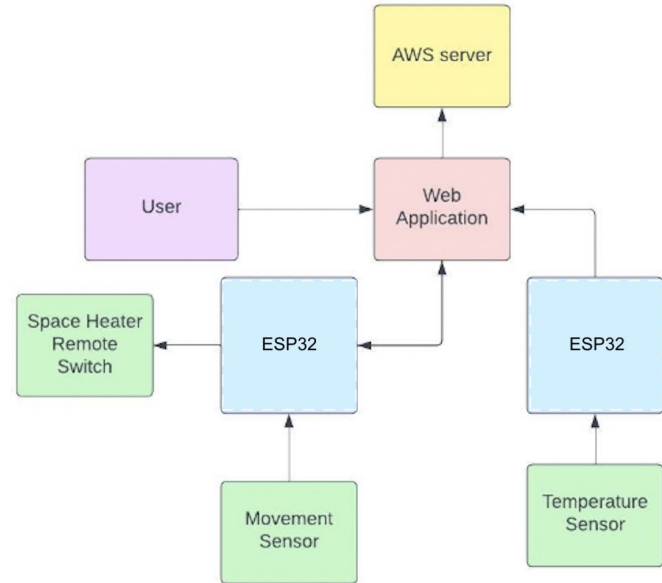

Use Case and Applications

- Our goal was to create remote controlled space heating system managed by a Web Application
- Our hope was to provide dynamic temperature control across different rooms for residents of older housing situations
- More specifically, allows for a safer, more financially efficient and flexible temperature regulation for off campus living situations
- With our web application, multiple users with different temperature preferences can use their corresponding space heaters to regulate personal temperature preferences at their space within a house

Solution Approach

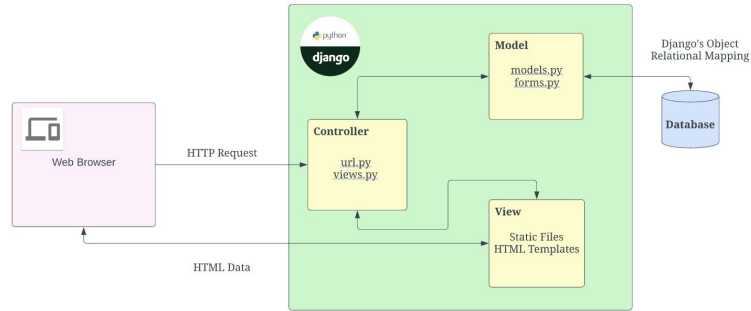

- Web App is the middle man between the AWS server and the devices
- A smart thermostat measures the temperature in the room.
- The WebApp maintains the temperature setting via a wireless smart plug
- Using infrared sensors to optimize load on breaker and save energy depending on whether someone is in the room
- Customizable temperature scheduling, setting for unoccupied rooms and breaker layouts on the Web app

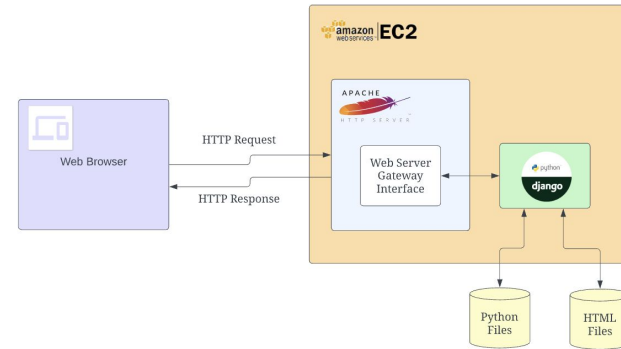

Original High Level Approach

Solution Approach: Software System Specification

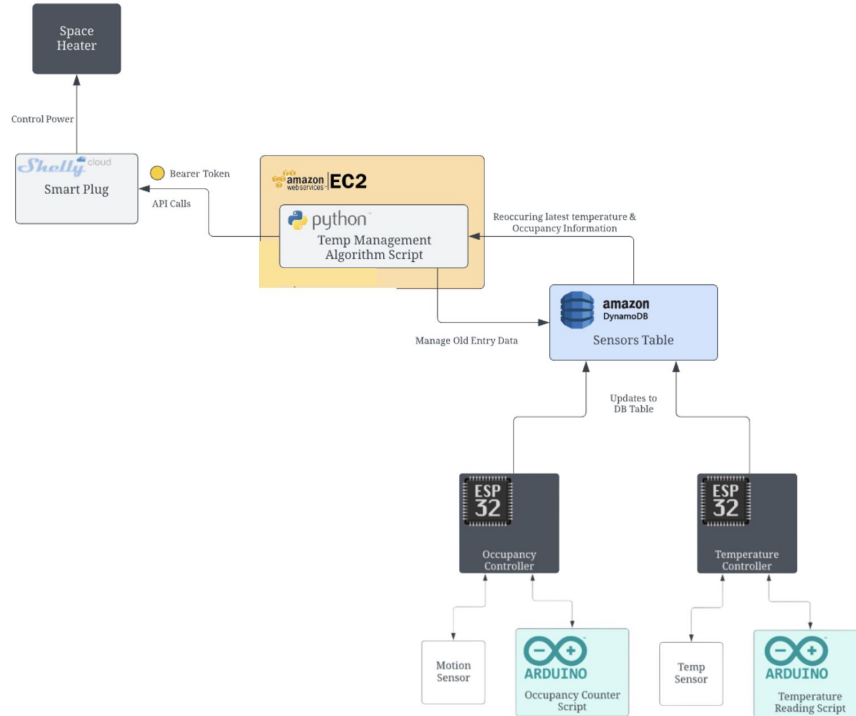

Web Application MVC-Architecture

Cloud Deployment of Web Application

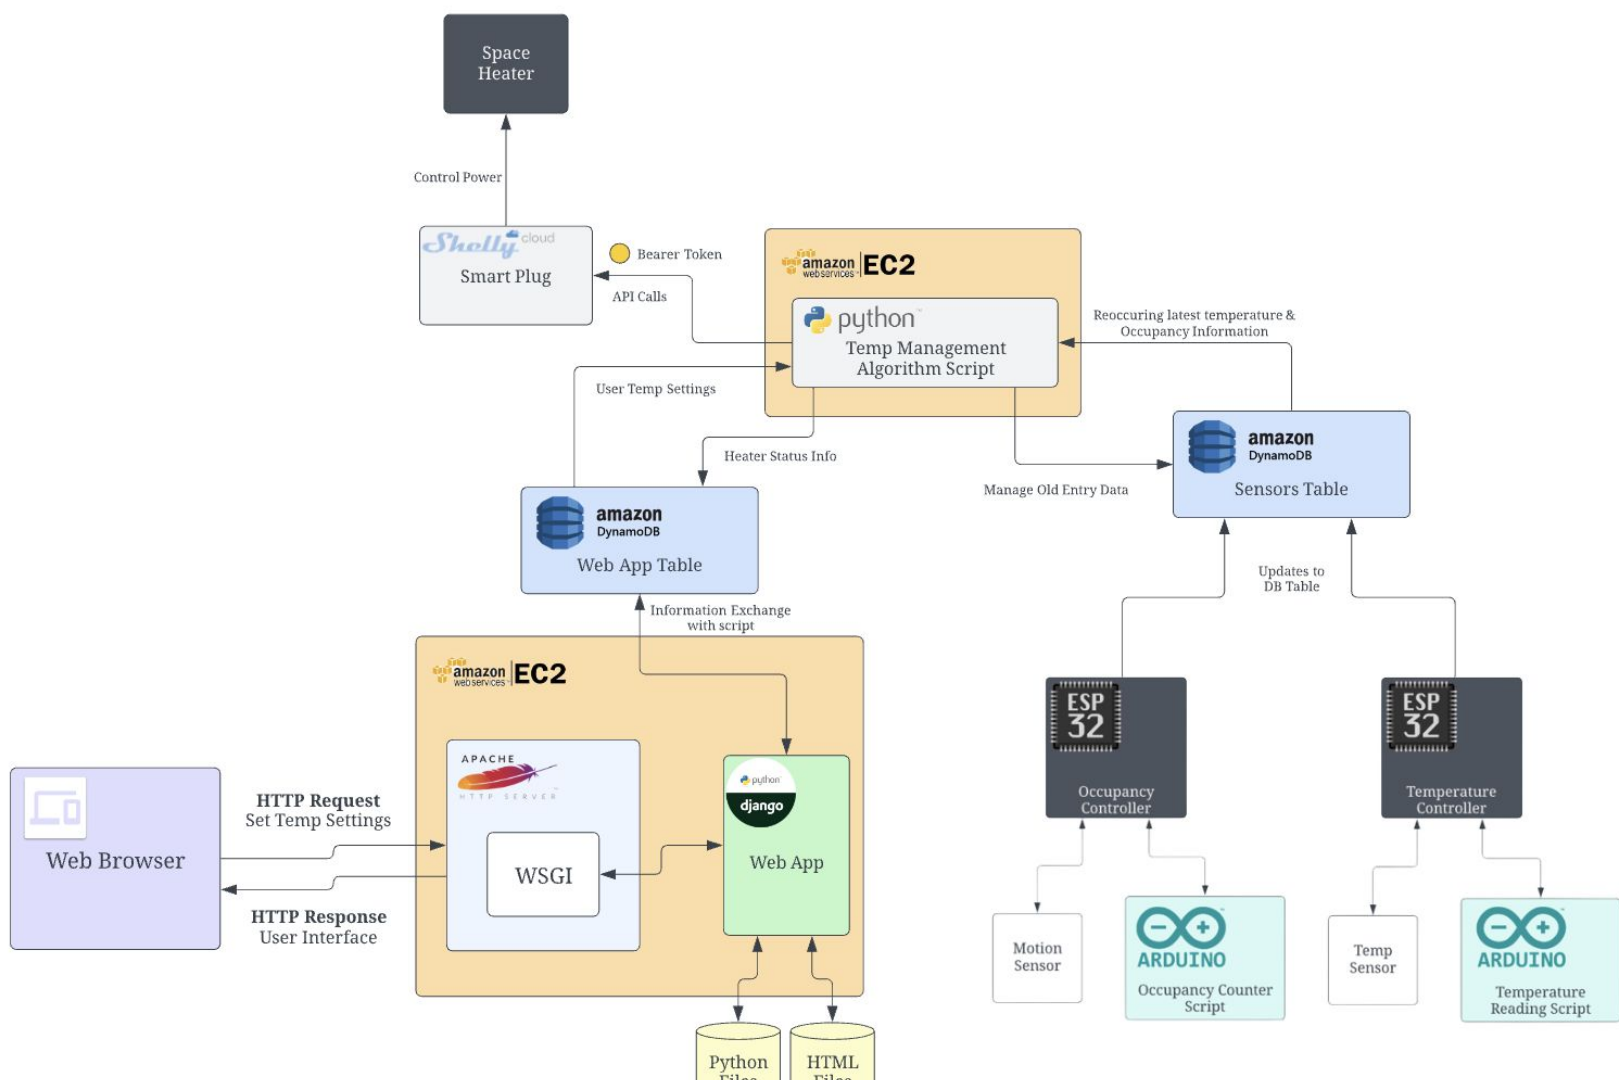

Solution Approach: Hardware System Specification

Solution Approach

- Through class discussions and deeper reflection over the course of the semester, we have identified additional considerations regarding public health, safety, and welfare, as well as global, cultural, social, environmental, and economic impact from our project
- Ethical issues like
 - Electrical fires caused from misuse/accidents
 - Unintentional increase in utility bills if preferences tampered with
 - Occupancy data can be used in a manner that invades user privacy concerns
- We have catered our implementation choices to reduce the possibility of these issues by
 - Simplifying our WebApp UI for less technological literate users
 - Choosing secure data storage options on the cloud like EC2 and DynamoDB

Test, Verification, and Validation: Use Case Requirements

Feature Tested	Quantitative Methodology	Result
Temperature Maintenance	Space Heater must maintain a temperature within a +/- 1.5F range	Success
User functionality	Manual and scheduling control	Success
Web App Usability	Satisfactory experience on survey questions with (1-5) ratings	Average 4.6 feedback

Test, Verification, and Validation: Design Requirements

Feature Tested	Quantitative Methodology	Result
Occupancy Sensors	Sensors must be able to detect a physical presence in the personal space with >95% accuracy	~90% reliability
Temperature Sensors	Sensors must be accurate within ± 0.5 F, tested with thermometer gun	Success, although 10-15 second delay in sensing temp changes
Toggling Heater Power depending on temperature	The heater must be turned on or off when the room temperature exceeds the user's preference within reasonable time limit.	Success, the heater is turned on or off within 5 seconds of temperature sensing

Test, Verification, and Validation: Design Requirements

Feature Tested	Quantitative Methodology	Result
Web App Capacity	Must be able to simultaneously support 50 accounts	Still Testing
Web App and Script integration	The web app and script database must sync within 5 seconds of new information on either end	Success, the script and web app was able to update each other.
Breaker Circuit Performance	When 2 heaters turned on within the same circuit, the next heater will be added onto the queue instead of turning on	Success, the script was able to add heater to queue within 2 secs.

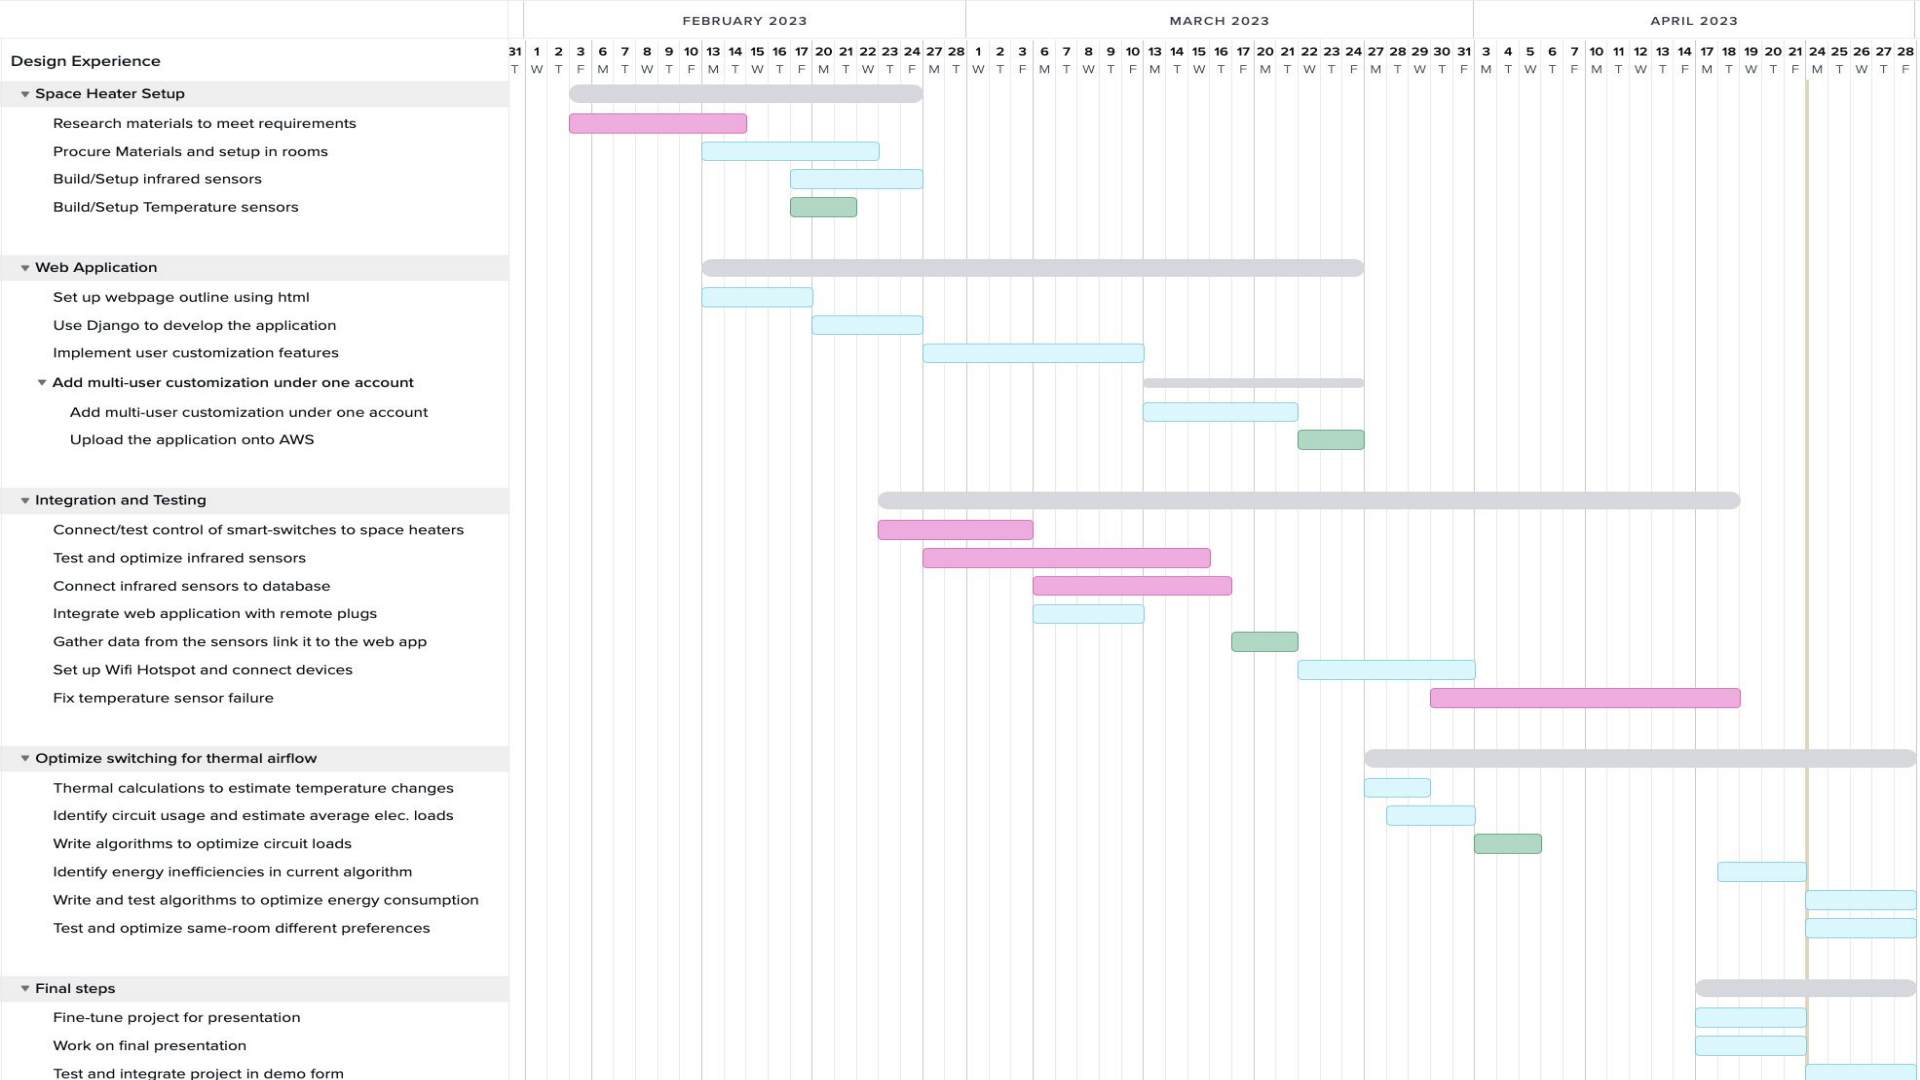

Test, Verification, and Validation: Trade Offs

Design Choice	Trade Off
Modularized python control script	Efficiency VS Cost
Extending motion sensors to side of door	Success rate VS more setup and points of failure
Adding 5V power module to temperature circuit instead of using 3.3V ESP output	Sensor actually working VS additional device cost and technically higher voltage than ESP input specs (potential but unlikely damage to ESP pins)
Using a Wifi Hotspot	Easier setup/backup for internet outage VS additional device cost
Adding max of two active heaters on one circuit	Preventing breakers going off in older houses VS potentially limiting heater output -> takes longer to reach desired heat

Project Management

Lessons Learned

- Perform more research on the resources and equipments before purchasing them
- Thoroughly understand all devices we are working with instead of trial and error
- Utilize other's experiences that are shared online
- Expect errors to occur and have a mitigation plans
