#### **Uses Case Review**

**Problem:** Laptops are not **ergonomic** and most computer stands require **manual** adjustment

Solution: a computer stand that automatically lifts and angles your laptop

- Also detects slouches
- Limits eye fatigue
- Displays posture progress

#### Quantitative Design Requirements

#### **User Interface**

- User can angle screen of PC to arbitrary angle
- Device weight < 4 lbs
- Device battery lasts 8 hrs
- Notifications for slouching and eye fatigue
- Progress tracking through GUI

#### Height & Angle Adjustment

- Stand lifts up to 12 in
- Stand angles PC up to 45 deg
- Max angle error < 5 degrees
- Max height error < 3 inches
- Slouch detection within 1 sec
- Ideal height reached < 5 sec

## Solution Approach Changes

# **Complete Solution: Hardware**

- Linear actuators are connected to an Adafruit Motor Shield V2
- Stepper motor is connected to a Big Easy Driver
- Arduino is connected to the laptop serially
- Shield and driver both use 12v power source

# **Ethical Considerations**

- We aim to help people fix their posture and prevent eye strain while using their laptops.
- Researched the optimal height and angle of a screen, as well as how long a person should be looking at a screen.
- We appropriately balanced the device to prevent it from harming the user.

# Design Tradeoffs

	Benefits	Drawbacks
High Torque Gearboxes 51:1 VS. 14:1	Stand requires 4.4 Nm of torque to lift. 14:1 gearbox only provides 3.0 Nm. Higher torque = higher range of motion.	Using the gearbox means that the motor will achieve less rotations per second, slowing down calibration.
Linear Actuators placed below the top plate	Can use linear actuators with greater change in distance without increasing the starting angle.	More complex mechanical design that must be able to support the weight of a laptop.
Neural Network-based posture detection	Rich decision boundary in neural nets means that a wide variety of poses can be classified.	Harder to set up, requires diverse training data.

### **Demo Solution**

 Using the app, the user will be calibrate the stand to the appropriate angle and height.

• Once calibrated, the user will exit the app and receive notifications about their posture.

# Height and Angle Accuracy

<u>Metrics</u>	<u>Test</u>	<u>Results</u>
Average Height Error	Use the height and angle adjustment process until "ideal" height and angle are reached.	0.95 inches (distance from center of the screen to user's eyeline)
Average Angle Error	Use the height and angle adjustment process until "ideal" height and angle are reached.	2.44 degrees (angle between screen and vertical)
Average Calibration Time	Use the GUI to calibrate different user's facial landmarks.	6.7 seconds
Average Adjustment Time	Opening laptop to varying angles, running the automatic angle adjustment, then manually increasing height.	33.56 seconds

# Requirements and Results:

<u>Requirement</u>	<u>Metric</u>	<u>Results</u>					
Height Range	Stand lifts up to 12 in	Met, up to 12 inches					
Height Accuracy	Max height error < 3 inches	Met, 0.95 inches					
Angle Accuracy	Max angle error < 5 degrees	Met, 2.44 degrees					
Angle range	Stand angles PC up to 45 deg	Met, up to 60 degrees					
Speed	Ideal height reached < 5 sec	Not met, 33.56 seconds					

#### **Posture Detection**

- Uses mix of shoulder and face landmarks
- Captures "ideal" landmark positions, then measures deviation
- If user strays too far from the ideal landmark positions, warning notification
