“Quality is free, but only to those who are willing to pay heavily for it.”

— DeMarco & Lister
Unit Testing

- Anti-Patterns:
  - Only system testing
  - Testing only “happy paths”
  - Forgetting to test “missing” code

- Unit testing
  - Test a single subroutine/procedure/method
    - Use low level interface (“unit” = “code module”)
  - Test both based on structure and on functionality
    - White box structural testing + Black box functional testing
  - This is the best way to catch boundary-based bugs
    - Much easier to find them here than in system testing

Test cases:
```
a = 0; b = 0;
a = -1; b = +1;
...
```
```
uint16_t proc(uint16_t a, uint16_t b)
{
    ...
    return(result);
}
```
Expected Test Results:
```
a = 0; b = 0;   ==> 0
a = -1; b = +2; ==> 1
...
Black Box Testing

- Tests designed based on behavior
  - But without knowledge of implementation
  - “Functional” or behavioral testing

- Test the what, but not the how
  - Example: cruise control black box test
    - Test operation at various speeds
    - BUT, no way to tell if special cases in code have been tested
  - Advantage: can be written only based on requirements or design
  - Disadvantage: difficult to exercise all code paths

- Black box Unit Testing
  - Tests based on detailed design (statechart, flowchart)

White Box Testing

- Tests designed with knowledge of software implementation
  - Often called “structural” testing
  - Sometimes: “glass box” or “clear box”

- Idea is to exercise software knowing how it is written
  - Example: cruise control white box test
    - Exercise every line of code
      » Tests that exercise both paths of every conditional branch statement
    - Test operation at every point in control loop lookup table

- Advantage: helps getting high structural code coverage
- Disadvantage: doesn’t prompt coverage of “missing” code
  - E.g., missing special case, missing exception handler
Coverage is a metric for how thorough testing is.

- Function coverage
  - What fraction of functions have been tested?

- Statement coverage
  - What fraction of code statements have been tested?
    - (Have you executed each line of code at least once?)

- Branch coverage (also Path Coverage)
  - Have both true and false branch paths been exercised?
  - Includes, e.g., testing the false path for `if (x) { ... }`

- MCDC coverage (next slide)

Getting to 100% coverage can be tricky
- Error handlers for errors that aren’t supposed to happen
- Dead (unused) code that should be removed from source
Modified Condition/Decision Coverage (MC/DC)

- Used by DO-178 for critical aviation software testing
- Exercise all ways to reach all the code
  - Each entry and exit point is invoked
  - Each decision tries every possible outcome
  - Each condition in a decision generates all outcomes
  - Each condition in a decision is shown to independently affect the outcome of the decision
- For example: “if (A == 3 || B == 4)” ➔ you need to test at least
  - A == 3 ; B != 4 (A causes branch, not masked by B)
  - A != 3 ; B == 4 (B causes branch, not masked by A)
  - A != 3 ; B != 4 (Fall-through case)
  - A == 3 ; B == 4 is NOT tested because it’s redundant (no new information gained)
- Might need trial & error test creation to generate 100% MCDC coverage

Unit Testing Coverage Strategies

- **Boundary tests:**
  - At borders of behavioral changes
  - At borders of min & max values, counter rollover
  - Time crossings: hours, days, years, ...

- **Exceptional values:**
  - NULL, NaN, Inf, null string, ...
  - Undefined inputs, invalid inputs
  - Unusual events: leap year, DST change, ...

- **Justify your level of coverage**
  - Trace to unit design
  - Get high code coverage
  - Define strategy for boundary & exception coverage
Cunit as an example framework

- **Test Suite**: set of related test cases
- **Test Case**: A procedure that runs one or more executions of a module for purpose of testing
- **Assertion**: A statement that determines if a test has passed or failed

Test case example: (http://cunit.sourceforge.net/doc/writing_tests.html#tests)

```c
int maxi(int i1, int i2)
{ return (i1 > i2) ? i1 : i2; }

…

void test_maxi (void)
{ CU_ASSERT(maxi(0,2) == 2); // this is both a test case + assertion
  CU_ASSERT(maxi(0, -2) == 0);
  CU_ASSERT(maxi(2,2) == 2); }
```
Best Practices For Unit Testing

- Unit Test every module
  - Use high coverage combination of white box & black box
  - Use a unit testing framework
    - Multiple simple tests better than one huge, complex test
  - Get good coverage of data values
    - Especially, validate all lookup table entries

- Unit Testing Pitfalls
  - Creating test cases is a development effort
    - Code quality for test cases matters; test cases can have bugs!
  - Difficult to test code can lead to dysfunctional “unit test” strategies
    - Breakpoint debugging is not an effective unit test strategy
    - Using Cunit to test 100K lines of code is not really unit testing
  - Pure white box testing is “doomed to succeed” (neglects “missing” code)
  - Don’t substitute unit tests for peer reviews and static analysis

WHAT'S MODIFIED CONDITION / DECISION COVERAGE TESTING?

HERE'S AN ANALOGY

IMAGINE A LIGHT CONTROLLED BY THREE SWITCHES...

IN MC/DC TESTING, WE NEED TO SHOW THAT EACH LIGHT SWITCH CAN INDEPENDENTLY TURN THE LIGHT ON OR OFF...

HOW DOES THAT APPLY TO SOFTWARE?

THE LIGHT CORRESPONDS TO THE DECISION AND THE SWITCHES CORRESPOND TO CONDITIONS
